7.2

Refer to the law data (bootstrap). Use the jackknife-after-bootstrap method to estimate the standard error of the bootstrap estimate of $se(R)$.

Solution

```
tbl_law <- bootstrap::law %>% as_tibble

# Bootstrap
n <- 100
boot_ <- tbl_law %>%
  modelr::bootstrap(n)

grp_boot <- boot_$strap %>% map(as_tibble)

# define function of R
r <- function(tib, col1=1, col2=2) {
  return(cor(tib[, col1], tib[, col2]))[[1]])
}

# jackknife
r_boot <- grp_boot %>% map_dbl(r)

jknf <- r_boot %>% jackknife(mean)

#result
jknf$jack.se

## [1] 0.01380424
```

7.3

Obtain a bootstrap t confidence interval estimate for the correlation statistic in Example 7.2 (law data in bootstrap).

Solution 1

First compute the \hat{R} .

```
r_mu <- r(tbl_law)
r_mu

## [1] 0.7763745
```

Then use bootstrap to compute the $\widehat{se\hat{R}^{(b)}}$ for every sample in 7.2.

```
# bootstrap for every sample
boot_grp_boot <- list()
grp_boot_grp_boot <- list()
sd_r_boot <- numeric(0)

for (i in 1:n){
  boot_grp_boot[i] <- modelr::bootstrap(grp_boot[[i]] %>%
                                         as.data.frame(), n)

  grp_boot_grp_boot[[i]] <- boot_grp_boot[[i]] %>%
    map(as_tibble) # convert to tibble

  sd_r_boot[[i]] <- grp_boot_grp_boot[[i]] %>%
    map_dbl(r) %>%
    sd()
}
```

Then Compute the t-statistics for every $\widehat{se\hat{R}^{(b)}}$ and compute the quantile of them.

```
t_boot <- (r_boot - r_mu) / sd_r_boot

alpha <- 0.1

Qt <- quantile(t_boot, c(alpha/2, 1-alpha/2), type = 1)
```

In the end, compute the sample standard deviation $\widehat{se\hat{R}}$ in the first resampling and compute the Bootstrap t CI.

```
se_boot <- sd(r_boot)

r_mu + Qt * se_boot

##          5%          95%
## 0.584726 1.262955
```

Solution 2

```
get_r <- function(data, indices, x, y) {

  d <- data[indices, ]
  r <- as.numeric(cor(d[x], d[y]))

  return(r)

}

get_r_var <- function(x, y, data, indices, its) {

  d <- data[indices, ]
  r <- cor(d[x], d[y]) %>%
    as.numeric()

  n <- nrow(d)
```

```

v <- boot::boot(
  x=x,
  y=y,
  R = its,
  data = d,
  statistic = get_r
) %>%
  pluck("t") %>%
  var(na.rm = TRUE)

return(c(r, v))
}

boot_t_out <- boot::boot(
  x = "LSAT", y = "GPA", its = 200,
  R = 1000, data = tbl_law, statistic = get_r_var
)
boot::boot.ci(boot_t_out, type="stud")

## BOOTSTRAP CONFIDENCE INTERVAL CALCULATIONS
## Based on 1000 bootstrap replicates
##
## CALL :
## boot::boot.ci(boot.out = boot_t_out, type = "stud")
##
## Intervals :
## Level      Studentized
## 95%      (-0.1278,  0.9741 )
## Calculations and Intervals on Original Scale

```

7.4

Refer to the air-conditioning data set *aircondit* provided in the *boot* package. The 12 observations are the times in hours between failures of airconditioning equipment [63, Example 1.1]:

3, 5, 7, 18, 43, 85, 91, 98, 100, 130, 230, 487.

Assume that the times between failures follow an exponential model $\text{Exp}(\lambda)$. Obtain the MLE of the hazard rate λ and use bootstrap to estimate the bias and standard error of the estimate.

Solution

```

data_air <- boot::aircondit

vec_air_time_diff <- data_air %>%
  as_vector() %>%
  diff()

vec_air_time_diff

## hours2 hours3 hours4 hours5 hours6 hours7 hours8 hours9 hours10 hours11
##      2      2     11     25     42      6      7      2     30     100
## hours12
##     257

```

Because the times between failures follow an exponential model $\text{Exp}(\lambda)$, so the likelihood function is

$$L(\lambda) = \prod \lambda e^{-\lambda X_i}$$

.

Considering that

$$\ln L(\lambda) = n \ln \lambda - \lambda \sum X_i$$

$$\frac{\partial \ln L}{\partial \lambda} = \frac{n}{\lambda} - \sum X_i = 0$$

so that

$$MLE(\lambda) = \frac{1}{\bar{X}_i}$$

```
MLE_exp <- function(data, i){
  return(1 / mean(data[i]))
}
boot_obj <- boot::boot(vec_air_time_diff, MLE_exp, n)
boot_obj

##
## ORDINARY NONPARAMETRIC BOOTSTRAP
##
##
## Call:
## boot::boot(data = vec_air_time_diff, statistic = MLE_exp, R = n)
##
##
## Bootstrap Statistics :
##      original      bias    std. error
## t1* 0.02272727 0.01103108 0.03093524
```

7.5

Refer to Exercise 7.4. Compute 95% bootstrap confidence intervals for the mean time between failures $1/\lambda$ by the standard normal, basic, percentile, and BCa methods. Compare the intervals and explain why they may differ.

Solution

```
boot::boot.ci(boot_obj, type=c("norm", "basic", "perc", "bca"))

## BOOTSTRAP CONFIDENCE INTERVAL CALCULATIONS
## Based on 100 bootstrap replicates
##
## CALL :
## boot::boot.ci(boot.out = boot_obj, type = c("norm", "basic",
##      "perc", "bca"))
##
## Intervals :
## Level      Normal          Basic
## 95%  (-0.0489, 0.0723 )  (-0.0541, 0.0341 )
##
## Level      Percentile      BCa
## 95%  ( 0.0113, 0.0996 )  ( 0.0103, 0.0673 )
```

```
## Calculations and Intervals on Original Scale
## Some basic intervals may be unstable
## Some percentile intervals may be unstable
## Warning : BCa Intervals used Extreme Quantiles
## Some BCa intervals may be unstable
```

7.7

Refer to Exercise 7.6. Efron and Tibshirani discuss the following example [84, Ch. 7]. The five-dimensional scores data have a 5×5 covariance matrix Σ , with positive eigenvalues $\lambda_1 > \dots > \lambda_5$. In principal components analysis,

$$\theta = \frac{\lambda_1}{\sum_{j=1}^5 \lambda_j}$$

measures the proportion of variance explained by the first principal component. Let $\hat{\lambda}_1 > \dots > \hat{\lambda}_5$ be the eigenvalues of $\hat{\Sigma}$, where $\hat{\Sigma}$ is the MLE of Σ . Compute the sample estimate

$$\hat{\theta} = \frac{\hat{\lambda}_1}{\sum_{j=1}^5 \hat{\lambda}_j}$$

Solution

```
tbl_scor <- bootstrap::scor
res_pca_scor <- prcomp(tbl_scor, scale = TRUE)

get_theta <- function(data, indices){
  d <- data[indices,]
  egn_v1 <- prcomp(d, scale=TRUE)$sdev ** 2
  return(egn_v1[[1]] / sum(egn_v1))
}

boot_scor <- boot::boot(tbl_scor, get_theta, n)
boot_scor

##
## ORDINARY NONPARAMETRIC BOOTSTRAP
##
##
## Call:
## boot::boot(data = tbl_scor, statistic = get_theta, R = n)
##
##
## Bootstrap Statistics :
##      original      bias    std. error
## t1* 0.636196 -1.549063e-05  0.04670585
```

7.8

Refer to Exercise 7.7. Obtain the jackknife estimates of bias and standard error of $\hat{\theta}$.

```
# Bootstrap
n <- 100
boot_ <- tbl_scor %>%
  modelr::bootstrap(n)

grp_boot <- boot_$strap %>% map(as_tibble)
```

```
# jackknife
r_boot <- grp_boot %>% map_dbl(get_theta)

jknf <- r_boot %>% jackknife(mean)

#result
jknf$jack.se

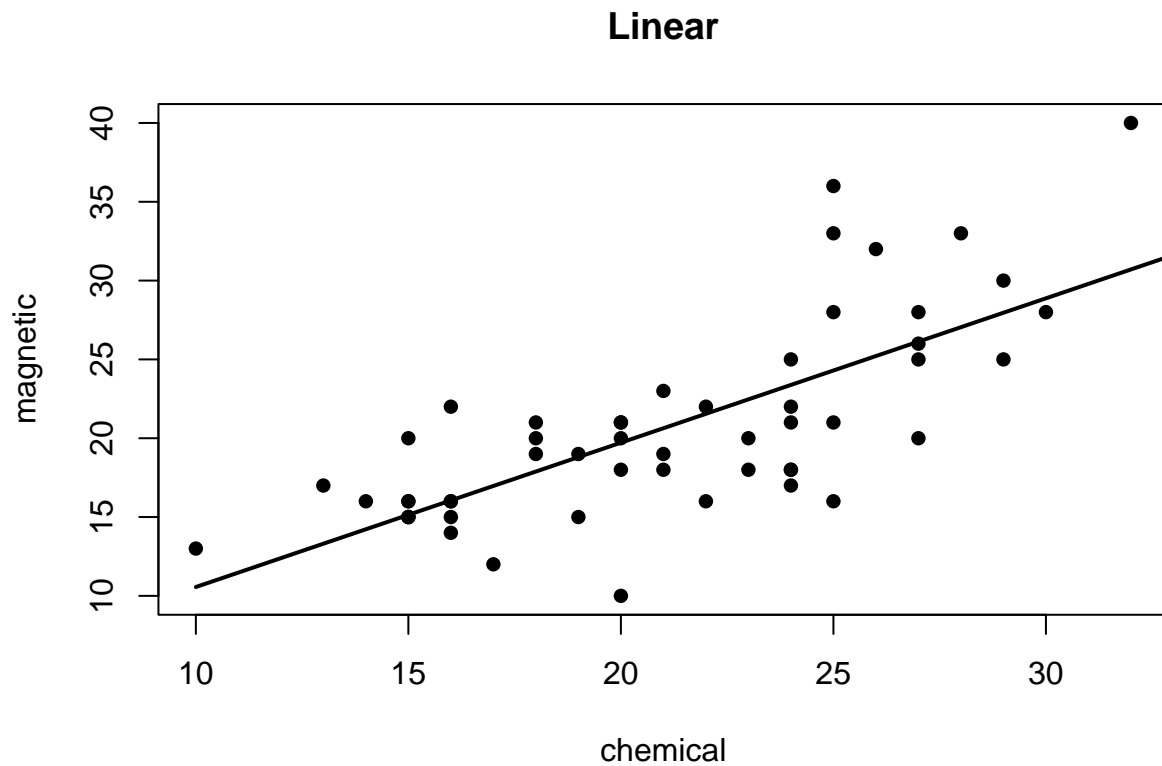

## [1] 0.004319266
```

7.10

In Example 7.18, leave-one-out (n-fold) cross validation was used to select the best fitting model. Repeat the analysis replacing the Log-Log model with a cubic polynomial model. Which of the four models is selected by the cross validation procedure? Which model is selected according to maximum adjusted R^2 ?

```
library(DAAG); attach(ironslag)
a <- seq(10, 40, .1) #sequence for plotting fits

L1 <- lm(magnetic ~ chemical)
plot(chemical, magnetic, main="Linear", pch=16)
yhat1 <- L1$coef[1] + L1$coef[2] * a
lines(a, yhat1, lwd=2)
```

```
L2 <- lm(magnetic ~ poly(chemical, 2, raw=TRUE))
plot(chemical, magnetic, main="Quadratic", pch=16)
yhat2 <- L2$coef[1] + L2$coef[2] * a + L2$coef[3] * a^2
lines(a, yhat2, lwd=2)
```

```
L3 <- lm(log(magnetic) ~ chemical)
plot(chemical, magnetic, main="Exponential", pch=16)
